Abstract — This paper gives a efficient algorithm for text localization and extraction for detection of both graphics and scene text in video images. The Text size is an vital design parameter whose dimension should be properly elected to make the method more robust and insensitive to various font shapes and sizes, styles, color/intensity, orientations, languages, text directions, background and effects of illumination, reflections, shadows, perspective distortion, and the density of image backgrounds. Basically it works in three steps: edge generation using Sobel edge detection mask, text localization using projection profiles based method and text segmentation, text recognition. The result of this paper demonstrates the capability of the proposed technique there by conducting experiments on the video images containing on a large group of complex video text images. The paper proves to be robust for various background complexities and text appearances. The method used in the paper has a high rate as good extraction result. This paper gives a method which has a high rate of good extraction results in complex video images and experimental results shows that the proposed technique gives better result than existing methods in terms of detection rate for large video image database with very few false alarms and reliable recall rate and precision rate.

Index Terms -Text Extraction, Video Images, Text Localization, Text Segmentation, Text Recognition.

I. INTRODUCTION AND RELATED WORKS

Texts in multimedia, natural scenes, video frames provide us with much useful information. However, due to the complex background in video frames, it is difficulties in locating and segmenting text in images. Text segmentation and extraction has been a well-investigated field over the last decade .Basically video text has two types: scene text which is exist in the real-world objects like indoor, outdoor, movie video text images and the superimposed text those are added in video like News video frames. Normally video frames have

surrounded complex background. The previous work approach in this field based upon the utilized features can be classified into three groups: connected component-based [2], edge-based [3, 4, 5] and texture-based [12] .

Shivakumara et al. [1] proposed a simple and novel method for detecting both graphic text and scene text in video images and introduces candidate text block selection to extract the text portion of the image in accordance with the results and rules based upon filters and edges. Gllavata et al. [2] proposed a method to localize and extract text from color images automatically. The component to be used after the transformation of color image into grayscale is the Y component. Earlier A Kumar et al. [3] proposed an edge based text extraction in images and video frames. This algorithm depends upon the line edge operator and the projection profile method is used to localize the text region better. A focus of attention based system for text region localization has been proposed by Liu et al [5]. For detecting text regions in an images the intensity profiles and spatial variance are used. Zhong Ji et al.[6] proposed a novel overlay and scene text detection method based on SVM and hybrid features, that is a wavelet transform coefficients features, gray-level co-occurrence matrix and oriented edge intensity ratio features, are employed to distinguish text from the background.

A fast and effective text detection approach is proposed by Xiaojun Li et al. [7] . The devised features based on the stroke maps in four directions are able to better represent the intrinsic characteristic of the text. Wonjun Kim et al.[8] proposed an overlay text detection and extraction from complex videos and compute the density of transition pixels and the consistency of texture around the transition pixels to distinguish the overlay text regions from other candidate regions. Shi Jianyong et al.[9] proposed an automatically detect and localize text regions in video frames, and transform the text regions into a binary image with white characters in a pure black background, which is a direct input to the OCR engine for recognition. Wu et al. [10] proposed a nonregion-based approach, which uses edges in the text

regions to form strokes, and then strokes are aggregated to form chips.

Gao and Tang [11] proposed to use horizontal and vertical projections of edges to localize text strings; however, it can only handle captions and cannot deal with complex text layouts. Some methods combine these two paradigms. Q. Ye et al.[12] Proposed , a novel coarse-to-fine algorithm that is able to locate text lines even under complex background using multiscale wavelet features and an SVM classifier is used to identify true text from the candidates based on the selected features. K. Kim et al. [13] present a novel texture-based method for detecting texts in images. A support vector machine (SVM) is used to analyze the textural properties of texts. No external texture feature extraction module is used. Q. Liu et al. [14] propose stroke filter for text localization in video images. The novelty of stroke filter is that it discovers the intrinsic characteristics of text by the analyzing the relationship between the local regions.

Our proposed method for image text extraction system (shown in Fig. 1) extracts a text region from an image. The rest of the paper is organized as follows. Section II is a literature of proposed algorithm and it describes the result and analysis in Section III. The conclusion process in Section IV.

II. PROPOSED ALGORITHM

The specific flow chart of the method proposed method is shown in figure 3. Basically it works in three steps: firstly edge generation using Sobel edge detection mask applied and after this, text localization using projection profiles based has been done. At last text segmentation and text recognition has been applied those are elaborated as under:

A. Edge map Generation –

Intensity image binarized image usually both have edge maps containing real edge pixel of rich contrasts region. Intensity image contains edge maps having scattered edge pixels as noise in an edge map and binarized image contains an edge map has another type of noise caused by binarization process. Enriched edge pixels of text are obtained by merging the two edge maps and get an edge map which contains minimum edge pixels of background. The proposed method allows better detection of intensity peaks that generally leads to a characterization of in text also it uses the magnitude of the second derivative of intensity as a measurement of edge strength. The distribution is relatively concentrated so that the richer the edge of the text near as well as smaller the distance of the text edges in the same region. In this step firstly line detection mask (1) is created to detect edges at Gx and Gy orientations converting video image to intensity based edge image using line edge operator shown in figure 2. Further more directional edge maps that are used to represent the vertical and horizontal directions edge density and edge strength up to now absolute value and complex magnitude has been determined and average map will be drawn next.

Obtain the minimum and the maximum gradient values in w over G(x,y) as follows

$$Min(x,y) = \min_{x_t y_t \in W(x,y)} (G(x_t, y_t)) \quad (1)$$

$$Max(x,y) = \max_{x_t y_t \in W(x,y)} (G(x_t, y_t)) \quad (2)$$

A global threshold (T) is calculated on the average value of the gradient difference as follows. First we compute the average gradient values. Using equation (1) and (2), compute GD(x,y) as follows

$$GD(x,y) = Max(x,y) - Min(x,y) \quad (3)$$

Then a pixel is classified as follows

$$(x,y) = \begin{cases} \text{Text Pixel} & , \text{if } (GD(x,y) > T) \\ \text{Non Text pixel} & , \text{Otherwise} \end{cases} \quad (4)$$

$$\begin{bmatrix} -1 & -1 & -1 \\ 2 & 2 & 2 \\ -1 & -1 & -1 \end{bmatrix} \quad \begin{bmatrix} -1 & 2 & -1 \\ -1 & 2 & -1 \\ -1 & 2 & -1 \end{bmatrix}$$

B. Text Localization –

Mean vertical edge is given by image with some short edge remained unconnected in the previous process. Erosion is used to eliminate these edges. This procedure helps to decrease the number of candidate regions for the next step and build the search process faster. Even after the elimination process these are a number of connected text and non connected text regions and the same process is repeated to search for text region from this image. So, narrow based on the geometric features of text such as height and width has been used in this process. Certainly, text in a label is organized in a strip of character in a straight line, tilted or curved nature with length higher than, frequently several times of its height. Depending of prescribed features, properties of the image in the entire region have been detected. If the measured height and width is found greater than the specified measurement; then it is eliminated from the text. Text strings are indicated by horizontal rectangular axes with high density and projection find such high density area. Many edges dense blocks are found containing multiple texts.

Figure 4. Horizontal projection profiles along with Video image.

Projection profile separates the blocks into single text line. The vector sum of the pixel intensity over each column and row given the horizontal and vertical projection profile. The horizontal (E_a) and vertical projection (E_b) of the processed edge map is found. Threshold (T) is termed as the average of the minimum and the maximum value of the vertical projection. Thereafter the row having sum of pixel intensities above the threshold are taken. According to the filter out edges incompatible with the text size: the edge maps of image and its binarized image are generated, and then the two edge maps are merged into one using our proposed edge map emerging method. The resulting edge map contains less edge pixels of surroundings but enriched edge pixels of text. In the second step, for evaluating the distribution of edge pixels in both horizontal and vertical direction projection profile method is used, thereafter thresholding methods applied to identify adjacent pixel row and column containing text pixels and these rows and columns compose the text region. In the third step, to check the text region contains real text or not. If the region contains real text, then the region is sent to the next extraction step, else if there is a false alarm, the current process would be terminated.

If $(E_a) < (T)$, Text regions in horizontal direction...
Else if $(E_b) < (T)$, Text regions in Vertical direction...
Else Non text regions

In this step only gives the horizontal projection of only those rows whose value is less than the value of average threshold. Some regions prove out to be too large or too small to be instances of text using projection profile. Therefore edges exceeding the maximum height and width are removed. Thus localization of the text regions of the image is achieved. The corresponding regions in the original image are taken and the text localized image is shown in figure 4 and figure 5.

Figure 5. Text Area Localized image.

C. Text Segmentation –

In this Step, Localized video image is converted to intensity based edge map using Sobel edge operator. It is followed by morphological process applied on edge based intensity image. Strong and weak sub bonds are diluted in these step .The regions of foreground pixel are enlarged by dilation operates done by adding pixels to the boundaries of the object in a binary image. The holes within the region become smaller while foreground pixels grow in size. So in this step segmented text area image are found shown in figure 6.

Figure 6. Text Area Segmentation image.

D. Text Recognition –

The segmented images are used for the extraction process in this step. The extracted text to be parsed & recognized by the Common OCR systems. The segmented text image is multiply the segmented text image with input binary image and text extraction result has been obtained in the form of white with pure black background pixels. The text extraction results are shown in figure 7.

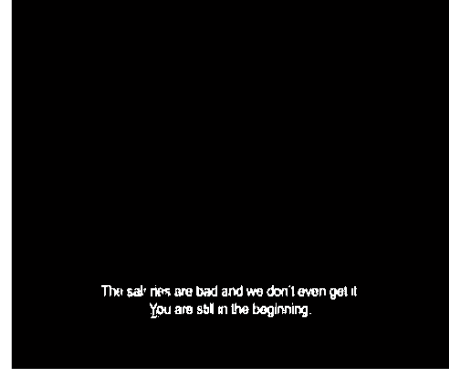

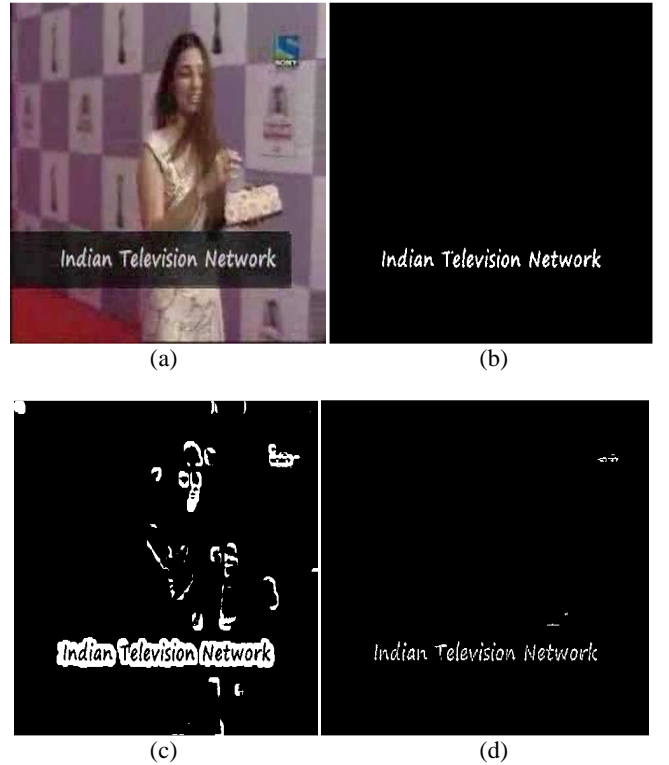

Figure 7. Text extraction result.

III. RESULT AND ANALYSIS

The method introduced in this paper was tested upon of color video text images. The experiments were performed by using a PC (Laptop: Intel Pentium 4 2.4GHz) with MATLAB. This method was evaluated with that of typical Xiaoping Liu et al. [5] and Gllavata *et al.* [2] with my previous algorithm [3] independently in term of effectiveness, quality and robustness respectively by measuring the computing time and by manually estimating the rates of recall rate and the precision rate. Here, 72 experimental video Text frames images are taken from internet randomly which are having 3501 total text words. Performance results for the eight videos are given in Table I.

TABLE I. RESULT OF THE DETECTED WORDS IN PROPOSED AND OTHER EXISTING METHOD

Image type	Total words	Detected words			
		Proposed Method	Liu method [5]	Kumar et al.[3]	Gllavata et al.[2]
News Images	1506	1415	1115	1345	1313
TV Images	1133	1122	815	1024	1001
Video images	862	851	521	813	648

TABLE II. RESULT OF THE FALSE POSITIVE IN PROPOSED AND OTHER EXISTING METHOD

Image type	False Positive			
	Proposed Method	Liu method [5]	Kumar et el.[3]	Gllavata et al.[2]
News Images	56	264	46	72
TV Images	83	443	42	35
Video images	21	470	73	33

TABLE III. PERFORMANCE OF THE RECALL RATE IN PROPOSED AND OTHER EXISTING METHOD

Image type	Recall Rate %			
	Proposed Method	Liu method [5]	Kumar et el.[3]	Gllavata et al.[2]
News Images	93.95	74.03	89.30	87.18
TV Images	99.02	71.56	90.37	88.34
Video images	98.72	60.44	94.13	75.17

TABLE IV. PERFORMANCE OF THE PRECISION RATE IN PROPOSED AND OTHER EXISTING METHOD

Image type	Precision Rate %			
	Proposed Method	Liu method [5]	Kumar et el.[3]	Gllavata et al.[2]
News Images	96.13	80.85	96.69	94.80
TV Images	93.11	64.78	96.06	96.62
Video images	97.59	52.57	91.76	95.15

From Fig. 8 ~ 10, it can see that the performance of our proposed method and other existing method on a wide variety of video frames. The performance of every method has been evaluated based on its precision and recall rates obtained overall.

$$\text{Recall Rate} = \frac{\text{Correctly Detected Words}}{\text{Correctly detected Words} + \text{False Negative}} * 100 \quad (5)$$

$$\text{Precision Rate} = \frac{\text{Correctly Detected Words}}{\text{Correctly detected Words} + \text{False Positive}} * 100 \quad (6)$$

According to table I~VI results obtained show that the proposed experiment result obtained a Racall rate of 93.95%, 99.02% and 98.72% and precision rate of 96.13%, 93.11% and 97.59% for News, commercial and video text images respectively. It can be noted from table II that Liu et al. [5] obtained an Racall rate of 74.03%, 71.56% and 60.44% and precision rate of 80.85%, 64.78% and 52.57%, Kumar et el. Obtained an Racall rate of 89.30%, 90.37% and 94.13% and precision rate of 96.69%, 96.06% and 91.76% and Gllavata et al. Obtained an Racall rate of 87.18%, 88.34% and 74.17% and precision rate of 94.80%, 96.62% and 95.15% for News, commercial and video text images respectively. The

proposed algorithm achieved a precision rate 95.49% and a recall 96.77% for the 72 video frames test images with average computed time 0.360 second /frames higher than other existing method.

TABLE V. AVERAGE PERFORMANCE OF THE PROPOSED AND EXISTING METHOD

Methods	Total Images	Recall %	Precision rate %	Average time (s)
Proposed Method	72	96.77	95.49	0.350
Liu Method		70.00	67.77	7.58
Kumar et al.		90.88	95.18	2.3
Gllavata et al.		84.60	95.48	19

An implementation of a typical Xiaoping Liu et al. [5] and Gllavata et al. [2] with my previous algorithm Kumar et al. [3] for Extraction the text in video images is done to verify the effectiveness of the proposed method. The compared experimental and performance results are shown in Table VI and V. Table I, II, III, IV and can conclude that the performance and processing time of the proposed method is far better than the implemented method in recall rate, precision rate and average time parameters.

TABLE VI. PERFORMANCE OF THE PROPOSED AND OTHER EXISTING METHOD

Methods	Recall rate %	Precision Rate %	Average Time (Image/s)
Proposed	96.77	95.49	0.360
Liu et al. [5]	70.27	65.85	7.58
Kumar et al.[3]	90.88	95.18	2.3
Gllavata et al. [4]	84.60	95.48	19
Ye et al. [11]	90.8%	-	10.1
Li et al. [13]	91.1%	-	12.9
Liu et al. [14]	91.3%	-	11.7
Lyu et al. [15]	82.13	90.22	-
Ye et al. [16]	94.2	-	8.3
Lienhart et al. [17]	94.3	-	2.2

IV. CONCLUSION

This paper gives an algorithm which is efficient for text extraction is complex video text images. The experimental results show that the chosen features are efficient with respect to the comparisons between text regions and non-text regions. Experiment results obtained a 96.64 % recall rate and precision rate 95.43 with average text extraction time is 0.350 second, which is far better than other previous and also presents robustness in text localization from low quality images. Still some text in images remains being extracted by proposed methods, which are more wide spaced text specially written in large font size and large gap between texts .In future, algorithm will be solve and satisfied spaced font and color effects in text detection.
